FOREWORD

The AIDS epidemic has put a spotlight on the many fault lines in society. Where there are inequalities, power imbalances, violence, marginalization, taboos and stigma and discrimination, HIV takes hold.

The AIDS epidemic is changing: in 2018, more than half of all new HIV infections were among key populations—sex workers, people who use drugs, gay men and other men who have sex with men, transgender people and prisoners—and their partners.

Globally, new HIV infections among young women aged 15–24 years were reduced by 25% between 2010 and 2018. This is good news, but of course it remains unacceptable that every week 6000 adolescent girls and young women become infected with HIV. The sexual and reproductive health and rights of women and young people are still too often denied.

Despite the scale of the challenges and the miles we must still travel together in the AIDS response, I am hopeful. The AIDS response has demonstrated what is possible when people organize and assert their rights. Around the world, people living with HIV and civil society have raised their voices and exerted leadership.

When communities organize and people empower each other, oppression can be replaced by rights and access to HIV services can be accelerated. Peer-to-peer counsellors, community health workers, door-to-door service providers, grass-root activists and networks of people living with or affected by HIV all have key roles to play in the response to HIV. As this report shows, community leadership in the AIDS response helps to ensure that HIV services are relevant to, and reach, the people who need them the most.

The world has committed to achieving the 2030 Agenda for Sustainable Development. As part of that, governments must protect and uphold the human rights of everyone. As the eyes and ears of the AIDS response, communities play a critical role in holding decision-makers to account and demanding political leadership.

For me, the AIDS response is about people—the young women who don't know how to keep themselves HIV-free, the men who won't or can't seek out health care, the transgender people who are discriminated against and the hundreds of thousands of people who die each year, even though HIV is preventable and treatable.

It is in our collective power to overcome the barriers that all too often stand in the way of better health—barriers such as user fees and other hidden costs, harmful laws, stigma and discrimination, lack of knowledge and gender-based violence.

FOR ME, THE AIDS RESPONSE IS ABOUT PEOPLE— THE YOUNG WOMEN WHO DON'T KNOW HOW TO KEEP THEMSELVES HIV-FREE, THE MEN WHO WON'T OR CAN'T SEEK OUT HEALTH CARE, THE TRANSGENDER PEOPLE WHO ARE DISCRIMINATED AGAINST AND THE HUNDREDS OF THOUSANDS OF PEOPLE WHO DIE EACH YEAR, EVEN THOUGH HIV IS PREVENTABLE AND TREATABLE.

While considerable progress has been made, there is a risk that we will lose momentum. If the world is to be on track to end AIDS by 2030, there must be adequate and predictable financing for development. But, for the first time since 2000, the resources available for the AIDS response globally have declined.

Ending AIDS is a life-saving investment that pays for itself many times over. Increases in donor and domestic funding are crucial. And the Global Fund to Fight AIDS, Tuberculosis and Malaria must be fully funded at its next replenishment.

We have the knowledge and tools we need to end AIDS. We cannot change the virus, but we can change inequalities, power imbalances, marginalization, taboos and stigma and discrimination. We can change behaviours and societies.

The change we need requires strong collective efforts by both governments and communities. Success is being achieved where policies and programmes focus on people, not diseases—policies and programmes that are designed with communities and that respond to the way that people live their lives.

This edition of UNAIDS data shows the results of some of those successes, but also the challenges that remain. It contains the very latest data on the world's response to HIV, consolidating a small part of the huge volume of data collected, analysed and refined by UNAIDS over the years. The full data set of information for 1990 to 2018 is available on aidsinfo.unaids.org.

Gunilla Carlsson UNAIDS Executive Director, a.i.

STATE OF THE EPIDEMIC

AT A GLANCE

Gains continue to be made against the epidemic, but those gains are getting smaller year-on-year. There has been steady progress in the reduction of AIDS-related deaths, but efforts to reach the 2020 target for reductions in HIV infections are clearly off-track.

Gains in eastern and southern Africa are driving global progress. In much of the rest of the world, there are worrying setbacks in key countries and entire regions. More than half of new HIV infections in 2018 were among key populations and their sexual partners.

An epidemic transition metric suggests that a diverse group of 19 countries are on the path to ending AIDS. Many more countries are not.

Overall progress against the HIV epidemic is measured through the calculation of estimates of new HIV infections and deaths from AIDS-related causes. Countries input the best available HIV surveillance and programmatic data into mathematical models to produce annual epidemiological estimates, and UNAIDS then aggregates country estimates into regional and global ones.

Each year, newly available data from countries and improvements in the models lead to adjustments in these estimates—not just year-on-year, but across the entire curve of annual estimates, from the current year back to the beginning of the epidemic. New evidence about the impact of antiretroviral therapy on mortality has been used to refine assumptions in the model, and this has produced lower estimates of AIDS-related deaths than the estimates from the previous year (see annex on methods).

Trends, however, remain similar: there has been steady global progress in the reduction of AIDS-related deaths

over the last decade, and more gradual progress in the reduction of new HIV infections.

These gains are getting smaller year-on-year, and the deadline for reaching the 2020 targets agreed by the United Nations General Assembly is getting closer and closer. Efforts to reduce HIV infections are clearly off-track, and while reductions in AIDS-related deaths are stronger, mortality-reduction targets could also be missed.

The global picture obscures a wide diversity of trends among countries and regions. In recent years, there have been worrying rises in annual HIV infections and AIDS-related mortality in key countries and entire regions. The largest reductions in annual HIV infections and AIDS-related deaths have occurred in the region hardest hit by the epidemic: eastern and southern Africa. Progress in the rest of the world, where HIV infections are predominantly among key populations, is considerably slower. The majority of global infections in 2018 were among key populations and their sexual partners.

A one third decline in AIDS-related deaths

The annual number of deaths from AIDS-related illness among people living with HIV (all ages) globally has fallen from a peak of 1.7 million [1.3 million–2.4 million] in 2004 to 770 000 [570 000–1 100 000] in 2018. Since 2010, AIDSrelated mortality has declined by 33%. Reaching the 2020 milestone of fewer than 500 000 deaths will require further declines of about 135 000 per year (Figure 2.1).

The global decline in deaths has largely been driven by progress in eastern and southern Africa, which is home

to 54% of the world's people living with HIV. AIDS-related mortality in the region declined by 44% from 2010 to 2018, to 310 000 [230 000–400 000]. By comparison, AIDS-related deaths in western and central Africa declined by 29%, to 160 000 [110 000–230 000] (Figure 2.2).

Outside of sub-Saharan Africa, there has been a 20% decline in AIDS-related deaths, to 300 000 [230 000–420 000] (Figure 2.3). AIDS-related deaths in the eastern Europe and central Asia and Middle East and North Africa regions have risen by 5% and 9%, respectively, over the eight-year period.

New HIV infections declining gradually

The annual number of new HIV infections globally continued to decline gradually in 2018. Since a peak of 2.9 million [2.3 million–3.8 million] new infections (all ages) in 1997, year-on-year declines have grown smaller. The annual number of new infections (all ages) since 2010 has declined from 2.1 million [1.6 million–2.7 million] to 1.7 million [1.6 million–2.3 million] in 2018, a 16% reduction that leaves the world far off the 2020 target of fewer than 500 000 new infections (Figure 2.4).

As is the case with AIDS-related mortality, the reduction in new HIV infections between 2010 and 2018 was strongest in eastern and southern Africa (28% decline). Progress was also made in the Caribbean (16% decline), western and central Africa (13% decline), western and central Europe and North America (12% decline), and Asia and the Pacific (9%). However, the annual number of new HIV infections has risen in eastern Europe and central Asia (29% increase), the Middle East and North Africa (10% increase) and Latin America (7% increase). Regional gains and setbacks combine to produce a flat 10-year trend in new infections outside of sub-Saharan Africa (Figure 2.5).

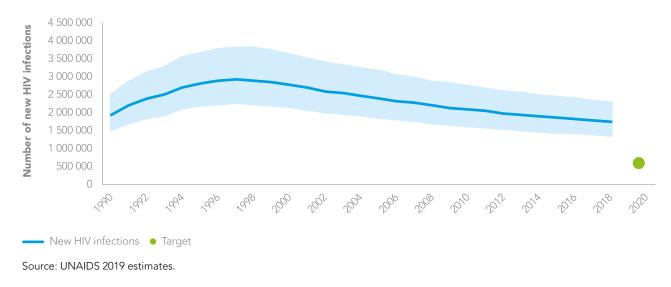

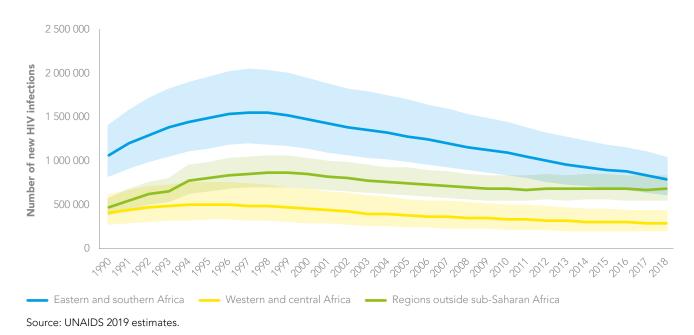

FIGURE 2.4 Number of new HIV infections, global, 1990–2018 and 2020 target

FIGURE 2.5 Number of new HIV infections, eastern and southern Africa, western and central Africa, and regions outside sub-Saharan Africa, 1990–2018

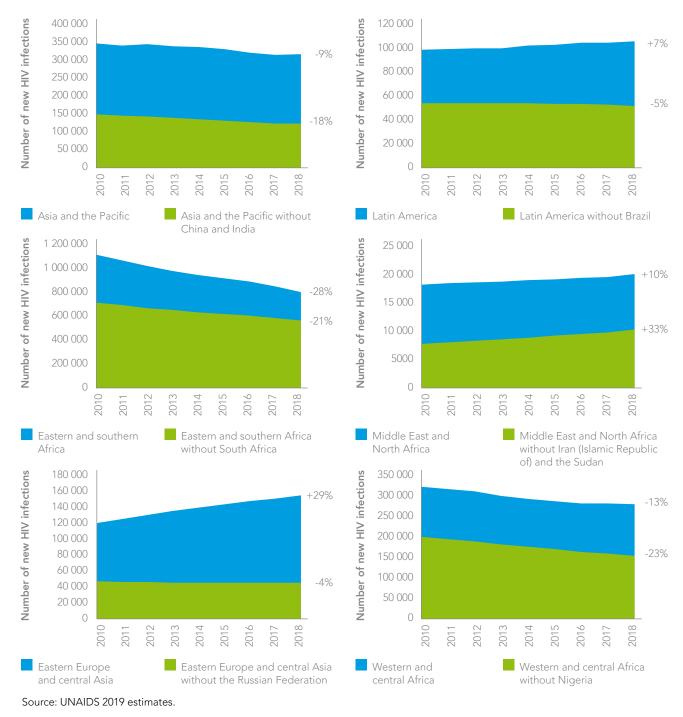

FIGURE 2.6 Trends in new HIV infections, by region, 2010–2018

Varied country-level trends can be obscured by regional averages, especially in regions where there are one or two countries that account for a majority of new HIV infections (Figure 2.6). In most cases, larger countries report lower performance than their smaller regional neighbours. A prime example is eastern Europe and central Asia, where the regional trend, excluding the Russian Federation (which accounted for 71% of the region's new HIV infections in 2018), is a 4% decline instead of a 29% increase, or in Latin America, where excluding Brazil results in a 5% decline in new HIV infections instead of a 7% increase. Similarly, the exclusion of China and India from Asia and the Pacific results in a more rapid 18% decline in new infections. In some cases, removing countries with larger epidemics reveals poorer performance in the rest of the region. The exclusion of South Africa from eastern and southern Africa results in a shallower decline of 21% (compared to 28%), and excluding the Islamic Republic of Iran and the Sudan in the Middle East and North Africa shows that new HIV infections in the other countries of the region increased by 33% (compared to 10%). ■

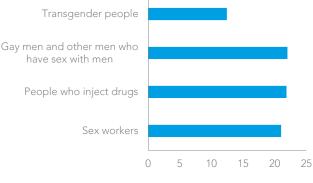

More than half of new infections are among key populations and their sexual partners

Key populations make up a small proportion of the general population, but they are at extremely high risk of HIV infection. Available data suggest that the risk of HIV acquisition among gay men and other men who have sex with men was 22 times higher in 2018 than it was among all adult men. Similarly, the risk of acquiring HIV for people who inject drugs was 22 times higher than for people who do not inject drugs, 21 times higher for sex workers than adults aged 15–49 years, and 12 times higher for transgender people than adults aged 15–49 years (Figure 2.7).

Strong progress in settings with high HIV prevalence in eastern and southern Africa, where HIV is predominantly transmitted within the general population—combined with a mixture of progress and setbacks in lower prevalence regions—has seen the global distribution of new HIV infections in 2018 cross a notable threshold: the majority of global infections were among key populations and their sexual partners. (Figure 2.8)

Gay men and other men who have sex with men accounted for an estimated 17% of new HIV infections globally, including more than half of new HIV infections in western and central Europe and North America,

FIGURE 2.7 Relative risk of HIV acquisition by subpopulations aged 15–49 compared to adults aged 15–49 in the total population, global, 2018

Relative risk

Note 1: Relative risk compares the incidence of two populations. Incidence for sex workers, people who inject drugs and transgender people was estimated and then divided by the global incidence of HIV among adults aged 15–49, estimated using the Spectrum models. Incidence for gay men and other men who have sex with men was estimated and then divided by the global incidence of HIV among male adults aged 15–49. Note 2: Transgender people estimates are derived only in the Asia and the Pacific, Caribbean, Latin America, and western and central Europe and North America regions. Note 3: Relative risk is interpreted as follows: sex workers have 21 times greater risk of acquiring HIV than adults aged 15–49 in the total population.

Source: UNAIDS special analyses using Spectrum 2019 results and 2019 Global AIDS Monitoring submissions, supplemented by data from published literature.

40% in Latin America, 30% in Asia and the Pacific, 22% in the Caribbean, 22% in eastern Europe and central Asia, 18% in the Middle East and North Africa, and 17% in western and central Africa.

People who inject drugs accounted for an estimated 12% of global infections, including 41% of new HIV infections in eastern Europe and central Asia, 37% of new infections in the Middle East and North Africa, and 13% in Asia and the Pacific. Sex workers accounted for 6% of global HIV infections, ranging from 14% in western and central Africa to less than 1% in western and central Europe and North America. Transgender women made up a small amount of new HIV infections globally, but they accounted for 5% of new HIV infections in Latin America and western and central Europe and North America Europe and North America.

UNAIDS DATA AVAILABLE AT AIDSinfo

The data in this document are just a sample of the data available from UNAIDS. Additional data presented in spreadsheets, maps and graphs are available at aidsinfo.unaids.org. These include:

- Estimates of new HIV infections, AIDS-related deaths and numbers of people living with HIV by different age groups and by sex.
- Additional Global AIDS Monitoring indicators on prevention, mother-to-child transmission, 90–90–90 targets and stigma and discrimination.
- A Key Population Atlas of maps with the latest available data on key populations at increased risk of HIV infection.
- An HIV financial dashboard that brings together into a single platform more than 85 different indicators on HIV financial resources.
- A database of policy indicators collected from countries using the National Commitments and Policy Instrument.
- Subnational data for selected countries
- Comparable data over multiple years and across countries, which can also be extracted to spreadsheets for further analysis.

Epidemic transition

Recent trends in new HIV infections and AIDSrelated mortality can only show part of the story of a country or regional HIV response. For example, the 2010 baseline for 2020 targets hides strong gains made by many countries before 2010 (compared to countries that scaled up their HIV responses more recently). Epidemic transition metrics have been developed by UNAIDS and its partners as complementary measures that countries can use to better track their progress towards ending AIDS as a public health threat.

One such metric, the incidence-prevalence ratio, uses the number of new HIV infections and the number of people living with HIV within a population to produce the inverse of the average duration of time a person lives with HIV in an epidemic that remains stable over many years. An epidemic transition benchmark of 3.0%—three HIV infections per 100 people living with HIV per year—corresponds to an average life expectancy after infection of 30 years (1). At this average life expectancy, the total population of people living with HIV will gradually fall if the country is below the 3% benchmark. However, if the number of new infections per 100 people living with HIV per year is greater than three, the population of people living with HIV will grow over time. The 3.0% benchmark thus combines two desirable conditions: long, healthy lives among people living with HIV and reductions in new infections.

The global incidence-prevalence ratio has declined from 11.2% in 2000 to 6.6% in 2010 to 4.6% in 2018, reinforcing the conclusion that important progress has been made against the epidemic. Despite this, the world is not yet on track to end AIDS as a public health threat by 2030. Western and central Europe and North America, where treatment coverage is generally high and a comprehensive set of HIV prevention options are available to a large percentage of people at risk of HIV, had an incidence-prevalence ratio of 3.1% in 2018, meaning that the UNAIDS benchmark has nearly been met in this high-income region. Performance in other regions ranged from 3.9% in eastern and southern Africa, 4.6% in the Caribbean, 5.4% in both Latin America and Asia and the Pacific, 5.5% in western and central Africa, 8.0% in the Middle East and North Africa, and 9.0% in eastern Europe and central Asia (Figure 2.17).

Source: UNAIDS 2019 estimates.

Eighteen countries achieved the 3.0% benchmark (Table 2.1), suggesting that the HIV responses in these countries are on the path to ending the AIDS epidemic. The diversity of regions, income levels and epidemics within these countries should be cause for hope: hyperepidemics, such as those in Botswana and Zimbabwe, are being brought under control, as are a range of more concentrated epidemics. Another 48 countries have incidence-prevalence ratios between 3.0% and 4.9%, suggesting considerable progress. Less encouraging are the number of countries that remain at 5.0% or above: in total, there are 70 such countries, including 13 that have a ratio above 10.0% a level that is associated with increasing HIV infections and large percentages of people living with HIV in these countries being denied antiretroviral therapy.

GLOBAL AND REGIONAL DATA

Global summary of the AIDS epidemic | 2018

Number of people living with HIV	Total Adults Women (15+ years) Children (<15 years)	37.9 million 36.2 million 18.8 million 1.7 million	[32.7 million–44.0 million] [31.3 million–42.0 million] [16.4 million–21.7 million] [1.3 million–2.2 million]
People newly infected with HIV in 2018	Total	1.7 million	[1.4 million–2.3 million]
	Adults	1.6 million	[1.2 million–2.1 million]
	Children (<15 years)	160 000	[110 000–260 000]
AIDS-related deaths in 2018	Total	770 000	[570 000–1.1 million]
	Adults	670 000	[500 000–920 000]
	Children (<15 years)	100 000	[64 000–160 000]

Global estimates for adults and children | 2018

People living with HIV	37.9 million [32.7 million-44.0 million]		
New HIV infections in 2018	1.7 million [1.4 million–2.3 million]		
AIDS-related deaths in 2018	770 000 [570 000–1.1 million]		

About 5000 new HIV infections (adults and children) a day 2018

- About 61% are in sub-Saharan Africa
- About 500 are among children under 15 years of age
- About 4400 are among adults aged 15 years and older, of whom:
 - almost 47% are among women
 - about 32% are among young people (15-24)
 - about 20% are among young women (15-24)

Global estimates for children (<15 years) | 2018

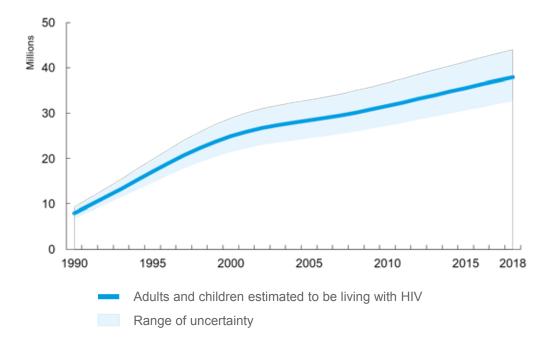

Children living with HIV	1.7 million [1.3 million–2.2 million]
New HIV infections in 2018	160 000 [110 000–260 000]
AIDS-related deaths in 2018	100 000 [64 000–160 000]

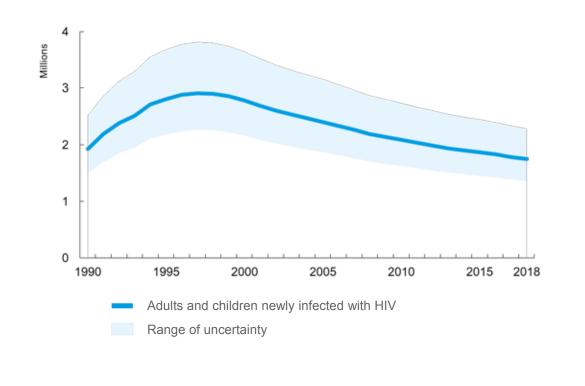

Regional HIV and AIDS statistics and features | 2018

	Adults and children living with HIV	Adults and children newly infected with HIV	Adult and child deaths due to AIDS

HIV TESTING AND TREATMENT CASCADE

ELIMINATION OF MOTHER-TO-CHILD TRANSMISSION

Percentage of pregnant women living with HIV	23%	>95%
accessing antiretroviral medicines	[17–31%]	[73–>95%]
Early infant diagnosis	36.1%	66.4%
Larry mant diagnosis	[27.3–50.2%]	[50.2–92.3%]

HIV COMORBIDITIES

Estimated number of incident tuberculosis cases among people living with HIV (2017)	66 000 [42 000 –95 000]
People living with HIV who started TB preventive therapy (2017)	
Cervical cancer screening of women living with HIV	
People coinfected with HIV and hepatitis B virus receiving combined treatment	
People coinfected with HIV and hepatitis C virus starting hepatitis C treatment	

Adults aged 15+ years with unsuppressed viral load	
Knowledge of HIV prevention among young people aged 15–24 years (2015)	
— Women	30.8%
— Men	30.2%
Condom use at last sex with a non-marital, non-cohabiting partner (2015)	
— Women	42%
— Men	46.5%
Women aged 15–49 years who have their demand for family planning satisfied by modern methods (2015)	55.5%
Men aged 15-49 years who are circumcised	
Voluntary medical male circumcisions performed according to national standards (2018)	311 891
People who received PrEP at least once during the reporting period (2018)	1934
Harm reduction	
 Use of sterile injecting equipment at last injection 	
 Needles and syringes distributed per person who injects 	
 Coverage of opioid substitution therapy 	
— Naloxone available (2019)	Yes
— Safe injection rooms available (2019)	No

HIV prevalence (15–49)	13.4 [12.2–14.2]	12.6 [11.4–13.3]	11.8 [10.6–12.7]

LAWS AND POLICIES

Laws criminalizing the transmission of, non- disclosure of or exposure to HIV transmission	No, but prosecutions exist based on general criminal laws
Criminalization of sex work among consenting adults	
Criminalization of same-sex sexual acts	Yes, penalty not specified
Drug use or possession for personal use is an offence	
Criminalization of transgender people	Neither criminalized nor prosecuted
Laws or policies restricting the entry, stay and residence of people living with HIV	No
Parental consent for adolescents to access HIV testing	Yes, for adolescents younger than 14 years
Spousal consent for married women to access sexual and reproductive health services	No
Mandatory HIV testing for marriage, work or residence permits or for certain groups	No

STIGMA AND DISCRIMINATION

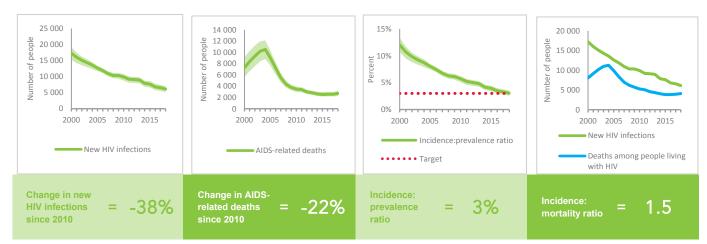

Percentage of women and men aged 15–49 years who report discriminatory attitudes	2007	2013
towards people living with HIV	23.1	13
Percentage of people living with HIV denied health services because of their HIV status in the last 12 months		

Percentage of people living with HIV who reported a health-care professional told others about their HIV status without their consent

VIOLENCE

Proportion of ever-married or partnered women aged 15–49 years who experienced	2013
physical or sexual violence from a male	
intimate partner in the past 12 months	20.2

LAWS AND POLICIES

Laws criminalizing the transmission of, non-Yes disclosure of or exposure to HIV transmission

Criminalization of sex work among consenting adults	Any criminalization or punitive regulation of sex work
Criminalization of same-sex sexual acts	Yes, imprisonment (up to 14 years)
Drug use or possession for personal use is an offence	Possession of drugs for personal use or drug use and/or consumption are specified as criminal offences
Criminalization of transgender people	Neither criminalized nor prosecuted
Laws or policies restricting the entry, stay and residence of people living with HIV	No
Parental consent for adolescents to access HIV testing	Yes, for adolescents younger than 18 years
Spousal consent for married women to access sexual and reproductive health services	No
Mandatory HIV testing for marriage, work or residence permits or for certain groups	No

residence permits or for certain groups

STIGMA AND DISCRIMINATION

Percentage of women and men aged 15-49 years who report discriminatory attitudes towards people living with HIV

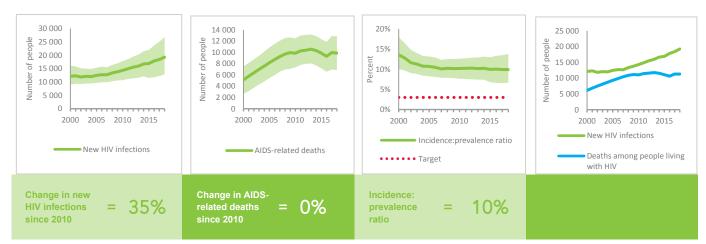

Percentage of people living with HIV denied health services because of their HIV status in the last 12 months

Percentage of people living with HIV who reported a health-care professional told others about their HIV status without their consent

VIOLENCE

Proportion of ever-married or partnered women aged 15-49 years who experienced physical or sexual violence from a male intimate partner in the past 12 months

LAWS AND POLICIES

Laws criminalizing the transmission of, non- disclosure of or exposure to HIV transmission	
Criminalization of sex work among consenting adults	
Criminalization of same-sex sexual acts	Yes, imprisonment (up to 14 years)
Drug use or possession for personal use is an offence	
Criminalization of transgender people	
Laws or policies restricting the entry, stay and residence of people living with HIV	No

...

Parental consent for adolescents to access HIV testing

Spousal consent for married women to access sexual and reproductive health services

Mandatory HIV testing for marriage, work or residence permits or for certain groups

STIGMA AND DISCRIMINATION

Percentage of women and men aged 15–49 years who report discriminatory attitudes towards people living with HIV

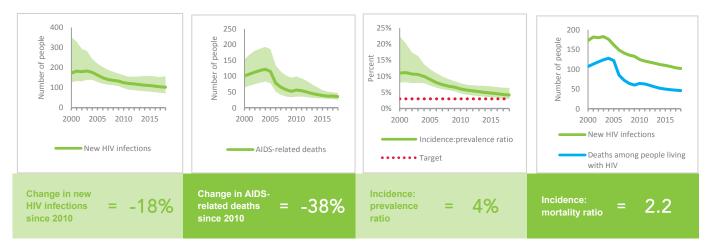

Percentage of people living with HIV denied health services because of their HIV status in the last 12 months

Percentage of people living with HIV who reported a health-care professional told others about their HIV status without their consent

VIOLENCE

Proportion of ever-married or partnered women aged 15–49 years who experienced physical or sexual violence from a male intimate partner in the past 12 months

LAWS AND POLICIES

Laws criminalizing the transmission of, non-No disclosure of or exposure to HIV transmission

Criminalization of sex work among consenting adults	Any criminalization or punitive regulation of sex work
Criminalization of same-sex sexual acts	No specific legislation
Drug use or possession for personal use is an offence	Possession of drugs for personal use or drug use and/or consumption are specified as criminal offences
Criminalization of transgender people	Neither criminalized nor prosecuted
Laws or policies restricting the entry, stay and residence of people living with HIV	No
Parental consent for adolescents to access HIV testing	Yes, for adolescents younger than 14 years
Spousal consent for married women to access sexual and reproductive health services	No
Mandatory HIV testing for marriage, work or residence permits or for certain groups	No

residence permits or for certain groups

STIGMA AND DISCRIMINATION

Percentage of women and men aged 15-49 years who report discriminatory attitudes towards people living with HIV

Percentage of people living with HIV denied health services because of their HIV status in the last 12 months

Percentage of people living with HIV who reported a health-care professional told others about their HIV status without their consent

VIOLENCE

Proportion of ever-married or partnered women aged 15-49 years who experienced physical or sexual violence from a male intimate partner in the past 12 months

Early infant diagnosis	7.1% [5.8–8.9%]	30.7% [26.2–37.3%]

HIV COMORBIDITIES

Estimated number of incident tuberculosis cases among people living with HIV (2017)	2000 [1500 –2500]
People living with HIV who started TB preventive therapy (2017)	
Cervical cancer screening of women living with HIV	
People coinfected with HIV and hepatitis B virus receiving combined treatment	
People coinfected with HIV and hepatitis C virus starting hepatitis C treatment	

Adults aged 15+ years with unsuppressed viral load	
Knowledge of HIV prevention among young people aged 15–24 years (2015)	
— Women	31.63%
— Men	28.52%
Condom use at last sex with a non-marital, non-cohabiting partner (2015)	
— Women	42.4%
— Men	70.5%
Women aged 15–49 years who have their demand for family planning satisfied by modern methods (2015)	86.8%
Men aged 15–49 years who are circumcised	Not applicable
Voluntary medical male circumcisions performed according to national standards	Not applicable
People who received PrEP at least once during the reporting period	
Harm reduction	
 Use of sterile injecting equipment at last injection 	
 Needles and syringes distributed per person who injects (2018) 	5
 Coverage of opioid substitution therapy 	
— Naloxone available (2019)	No
— Safe injection rooms available (2019)	No

LAWS AND POLICIES

Laws criminalizing the transmission of, non- disclosure of or exposure to HIV transmission	No, but prosecutions exist based on general criminal laws
Criminalization of sex work among consenting adults	Any criminalization or punitive regulation of sex work
Criminalization of same-sex sexual acts	Yes, imprisonment (up to 14 years)
Drug use or possession for personal use is an offence	The law allows possession of a certain amount of drugs
Criminalization of transgender people	Criminalized
Laws or policies restricting the entry, stay and residence of people living with HIV	Yes
Parental consent for adolescents to access HIV testing	No
Spousal consent for married women to access sexual and reproductive health services	No
Mandatory HIV testing for marriage, work or	

residence permits or for certain groups

STIGMA AND DISCRIMINATION

Percentage of women and men aged 15-49 years who report discriminatory attitudes towards people living with HIV

Percentage of people living with HIV denied health services because of their HIV status in the last 12 months

Percentage of people living with HIV who reported a health-care professional told others about their HIV status without their consent

VIOLENCE

Proportion of ever-married or partnered women aged 15-49 years who experienced physical or sexual violence from a male intimate partner in the past 12 months

LAWS AND POLICIES

Laws criminalizing the transmission of, non-	
disclosure of or exposure to HIV transmission	

Criminalization of sex work among consenting adults

Criminalization of same-sex sexual acts	Yes, imprisonment (up to 14 years)

...

...

Drug use or possession for personal use is an offence

Criminalization of transgender people

Laws or policies restricting the entry, stay and $$_{\mbox{Yes}}$$ residence of people living with HIV

Parental consent for adolescents to access HIV testing

Spousal consent for married women to access sexual and reproductive health services

Mandatory HIV testing for marriage, work or residence permits or for certain groups

STIGMA AND DISCRIMINATION

Percentage of women and men aged 15–49 years who report discriminatory attitudes towards people living with HIV

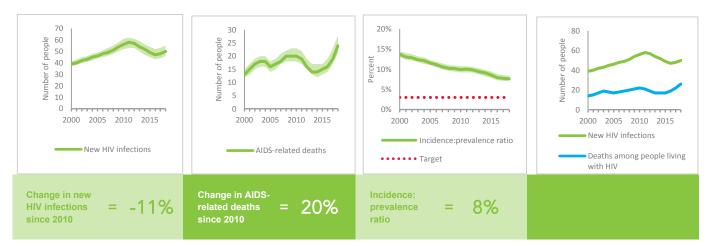

Percentage of people living with HIV denied health services because of their HIV status in the last 12 months

Percentage of people living with HIV who reported a health-care professional told others about their HIV status without their consent

VIOLENCE

Proportion of ever-married or partnered women aged 15–49 years who experienced physical or sexual violence from a male intimate partner in the past 12 months

LAWS AND POLICIES

Laws criminalizing the transmission of, nondisclosure of or exposure to HIV transmission

Criminalization of sex work among consenting adults	Any criminalization or punitive regulation of sex work
Criminalization of same-sex sexual acts	Laws penalizing same-sex sexual acts have been decriminalized or never existed
Drug use or possession for personal use is an offence	The law allows possession of a certain amount of drugs
Criminalization of transgender people	Neither criminalized nor prosecuted
Laws or policies restricting the entry, stay and residence of people living with HIV	Yes
Parental consent for adolescents to access HIV testing	Yes, for adolescents younger than 16 years
Spousal consent for married women to access sexual and reproductive health services	No

Mandatory HIV testing for marriage, work or residence permits or for certain groups

STIGMA AND DISCRIMINATION

Percentage of women and men aged 15–49 years who report discriminatory attitudes towards people living with HIV

Percentage of people living with HIV denied health services because of their HIV status in the last 12 months

Percentage of people living with HIV who reported a health-care professional told others about their HIV status without their consent

VIOLENCE

Proportion of ever-married or partnered women aged 15–49 years who experienced physical or sexual violence from a male intimate partner in the past 12 months

LAWS AND POLICIES

Laws criminalizing the transmission of, nondisclosure of or exposure to HIV transmission

Criminalization of sex work among consenting adults	Any criminalization or punitive regulation of sex work
Criminalization of same-sex sexual acts	Laws penalizing same-sex sexual acts have been decriminalized or never existed
Drug use or possession for personal use is an offence	No
Criminalization of transgender people	Neither criminalized nor prosecuted
Laws or policies restricting the entry, stay and residence of people living with HIV	No
Parental consent for adolescents to access HIV testing	Yes, for adolescents younger than 18 years
Spousal consent for married women to access sexual and reproductive health services	No

Mandatory HIV testing for marriage, work or residence permits or for certain groups

STIGMA AND DISCRIMINATION

Percentage of women and men aged 15–49 years who report discriminatory attitudes	2018
towards people living with HIV	68.5
Percentage of people living with HIV denied health services because of their HIV status in the last 12 months	
Percentage of people living with HIV who	

Percentage of people living with HIV who reported a health-care professional told others about their HIV status without their consent

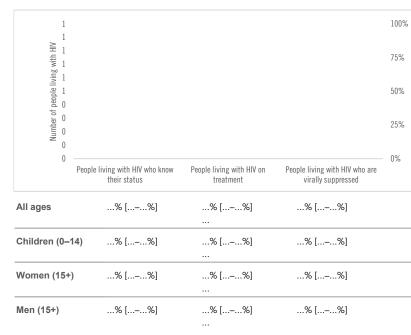

VIOLENCE

Proportion of ever-married or partnered women aged 15–49 years who experienced physical or sexual violence from a male intimate partner in the past 12 months

KEY POPULATIONS

	Sex workers	Gay men and other men who have sex with men	People who inject drugs	Transgender people	Prisoners
Estimated size of population

ANNEX ON METHODS

PART I. METHODS FOR DERIVING UNAIDS HIV ESTIMATES

INTRODUCTION

UNAIDS annually provides revised global, regional and country-specific modelled estimates using the best available epidemiological and programmatic data to track the HIV epidemic. Modelled estimates are required because it is impossible to count the exact number of people living with HIV, people who are newly infected with HIV or people who have died from AIDS-related causes in any country: doing so would require regularly testing every person for HIV and investigating all deaths, which is logistically impossible and ethically problematic. Modelled estimates—and the lower and upper bounds around these estimates provide a scientifically appropriate way of describing HIV epidemic levels and trends.

PARTNERSHIPS IN DEVELOPING METHODS FOR UNAIDS ESTIMATES

Country teams use UNAIDS-supported software to develop estimates annually. The country teams are primarily comprised of demographers, epidemiologists, monitoring and evaluation specialists, and technical partners. The software used to produce the estimates is Spectrum, which is developed by Avenir Health, and the Estimates and Projections Package, which is developed by the East–West Center.¹ The UNAIDS Reference Group on Estimates, Modelling and Projections provides technical guidance on the development of the HIV component of the software.²

¹ More information on Avenir Health can be found at www.avenirhealth.org. The East–West Center website can be found at www.eastwestcenter.org.

² For more on the UNAIDS Reference Group on Estimates, Modelling and Projections, please visit www.epidem.org.

A BRIEF DESCRIPTION OF METHODS USED BY UNAIDS TO CREATE ESTIMATES³

For countries where HIV transmission is high enough to sustain an epidemic in the general population, available epidemiological data typically consist of HIV prevalence results from pregnant women attending antenatal clinics and from nationally representative population-based surveys. Many countries have historically conducted HIV sentinel surveillance among women attending antenatal clinics, which requires collecting data from a selection of clinics for a few months every few years. More recently, a number of countries have stopped conducting sentinel surveillance among pregnant women and are now using the data from the routine HIV tests conducted when pregnant women attend antenatal clinics and are tested for HIV. These data avoid the need to conduct a separate surveillance effort, and they provide a complete set of data from all clinics across the country instead of samples from specific sites.

The trends from pregnant women at antenatal clinics, whether done through surveillance or routine data, can be used to inform estimates of national prevalence trends, whereas data from population-based surveyswhich are conducted less frequently but have broader geographical coverage and also include men-are more useful for informing estimates of national HIV prevalence levels. Data from these surveys also contribute to estimating age- and sex-specific HIV prevalence and incidence levels and trends. For a few countries in sub-Saharan Africa that have not conducted population-based surveys, HIV prevalence levels are adjusted based on comparisons of antenatal clinic surveillance and population-based survey data from other countries in the region. HIV prevalence trends and numbers of people on antiretroviral therapy are then used to derive an estimate of HIV incidence trends.

Historically, countries with high HIV transmission have produced separate HIV prevalence and incidence trends for rural and urban areas when there are wellestablished geographical differences in prevalence. To better describe and account for further geographical heterogeneity, an increasing number of countries have produced subnational estimates (e.g., at the level of the province or state) that, in some cases, also account for rural and urban differences. These subnational or rural–urban estimates and trends are then aggregated to obtain national estimates.

In the remaining countries, where HIV transmission occurs largely among key populations at higher risk of HIV and the epidemic can be described as low-level, the estimates are derived from either surveillance among key populations and the general, low-risk population, or from HIV case reporting data, depending on which data are most reliable in a particular country. In countries with high-quality HIV surveillance data among the key populations, the data from repeated HIV prevalence studies that are focused on key populations are used to derive national estimates and trends. Estimates of the size of key populations are increasingly derived empirically in each country; when studies are not available, they are derived based on regional values and consensus among experts. Other data sources-including HIV case reporting data, population-based surveys and surveillance among pregnant women-are used to estimate the HIV prevalence in the general, low-risk population. The HIV prevalence curves and numbers of people on antiretroviral therapy are then used to derive national HIV incidence trends.

For most countries in western and central Europe and North America—and many countries in Latin America, the Caribbean, and the Middle East and North Africa that have insufficient HIV surveillance or survey data, but that have robust disease reporting systems— HIV case reporting and AIDS-related mortality data from vital registration systems are directly used to inform trends and levels in national HIV prevalence and incidence. These methods also allow countries to take into account evidence of underreporting or reporting delays in HIV case report data, as well as the misclassification of deaths from AIDS-related causes.

In all countries where UNAIDS supports the development of estimates, assumptions about the effectiveness of HIV programme scale-up and patterns of HIV transmission and disease progression are used to obtain the following age- and sex-specific estimates of people living with HIV, people newly infected with HIV, people dying from AIDS-related illness and other important indicators (including treatment programme coverage statistics). These assumptions are based on

³ A full description of the methods used for the 2019 estimates is available in the July 2019 supplement of the journal AIDS.

systematic literature reviews and analyses of raw study data by scientific experts. Demographic population data, including fertility estimates, are derived from the United Nations Population Division's World Population Prospects 2017 data files.

Selected inputs into the model—including the number of people on antiretroviral therapy and the number of women accessing services for the prevention of mother-to-child transmission of HIV by type of regimen—are reviewed and validated in partnership with the United Nations Children's Fund (UNICEF), the World Health Organization (WHO), the Government of the United States of America, the Global Fund to Fight AIDS, Tuberculosis and Malaria, and other partners. Final country-submitted files containing the modelled outputs are reviewed at UNAIDS to ensure that the results are comparable across regions and countries and over time.

In 2019, sub-national estimates were created and used by more than 25 countries for internal planning purposes. The methods for producing robust sub-national estimates varies by country and depends primarily on the availability of sub-national data. Four methods were used (Mathematical modelling, Model-based geo-statistics, small area estimation and direct estimates from prevalence surveys) to derive the sub-national estimates. The methods to generate robust sub-national estimates are still being refined.

UNCERTAINTY BOUNDS AROUND UNAIDS ESTIMATES

The estimation software calculates uncertainty bounds around each estimate. These bounds define the range within which the true value lies (if it can be measured). Narrow bounds indicate that an estimate is precise, while wide bounds indicate greater uncertainty regarding the estimate.

In countries using HIV surveillance data, the quantity and source of the data available partly determine the precision of the estimates: countries with more HIV surveillance data have smaller ranges than countries with less surveillance data or smaller sample sizes. Countries in which a national population-based survey has been conducted generally have smaller ranges around estimates than countries where such surveys have not been conducted. Countries producing subnational estimates at the provincial level have wider ranges. In countries using HIV case reporting and AIDSrelated mortality data, the number of years of data and the magnitude of the cases reported or AIDS-related deaths observed will contribute to determining the precision of the estimate.

The assumptions required to arrive at the estimate also contribute to the extent of the ranges around the estimates: in brief, the more assumptions, the wider the uncertainty range, since each assumption introduces additional uncertainties. For example, the ranges around the estimates of adult HIV prevalence are smaller than those around the estimates of HIV incidence among children, which require additional data on prevalence among pregnant women and the probability of mother-to-child HIV transmission that have their own additional uncertainty.

UNAIDS is confident that the actual numbers of people living with HIV, people who are newly infected with HIV or people who have died from AIDS-related causes lie within the reported ranges. Over time, more and better data from countries will steadily reduce uncertainty.

IMPROVEMENTS INCLUDED IN THE 2019 UNAIDS ESTIMATES MODEL

Country teams create new Spectrum files every year. The files may differ from one year to the next for two reasons. First, new surveillance and programme data are entered into the model; this can change HIV prevalence and incidence trends over time or antiretroviral therapy coverage rates, including for past years. Second, improvements are incorporated into the model based on the latest available science and statistical methods, which leads to the creation of more accurate trends in HIV incidence. Due to these improvements to the model and the addition of new data to create the estimates, the results from previous years cannot be compared with the results from this year. A full historical set of estimates are created each year, however, enabling a description of trends over time.

Between the 2018 estimates and the 2019 estimates, the following changes were applied to the model

under the guidance of the UNAIDS Reference Group on Estimates, Modelling and Projections and based on the latest scientific evidence.

New incidence estimation model for generalized epidemics

In 2019, a new model (R-hybrid) was introduced that uses an improved function to estimate the rate of HIV infection during different phases of the HIV epidemic. For estimating infections early in the epidemic, when data were relatively sparse, the new model has a simple structure that follows the consistent pattern across countries of exponential growth, peak and decline. For more recent years the model has more flexibility to follow the increased amount of data to shape the trends in new infections. This new model improves the fit to existing prevalence data, especially for recent routine testing data from antenatal clinics.

The previous incidence estimation model used in generalized epidemics assumed HIV prevalence stabilized at the last observed value. The impact of adopting the R-hybrid model will be minimal in countries with substantial historical surveillance data and recent surveys, but in countries with few data points early in the epidemic or in recent years, the R-hybrid model should improve the fit to available data.

Mortality among people not receiving treatment

Assumptions of the risk of mortality among people not receiving treatment were reduced based on high quality vital registration data where fewer AIDS-related deaths among the untreated HIV positive adults were recorded than predicted by Spectrum.

The impact of this change is lower mortality rates among people not receiving treatment and fewer AIDS-related deaths overall.

Mortality among people receiving antiretroviral therapy

Previously, the model assumed that mortality rates following antiretroviral therapy initiation are constant over time, conditional on age, sex, baseline CD4 count and duration on treatment. However, recent studies have shown that these rates have declined over time, even after controlling for temporal changes in baseline CD4 count and treatment duration. A temporal reduction in mortality was included in the model as estimated from the IeDEA cohort data.

IeDEA data were also reanalysed for Latin America, North America, and Asia and the Pacific with improved assumptions about mortality among those lost to follow-up. This resulted in substantially lower mortality rates than previously estimated. In countries with highquality mortality data, on- and off-treatment mortality were adjusted to match AIDS-related deaths. An option to specify allocation of treatment disproportionately to either those with low CD4 counts or according to eligibility criteria was introduced to better match the low number of AIDS-related mortality data observed in western and central Europe.

Fertility among women living with HIV

The 2019 Spectrum model included updated parameters about the fertility of women living with HIV who were not receiving antiretroviral therapy. The new parameters led to higher fertility among women living with HIV early in the epidemic, before treatment was provided to HIV-positive pregnant women. This adjustment increased historical estimates of children living with HIV.

In the 2019 model, HIV prevalence data from routine testing among pregnant women at antenatal clinics were used to calibrate the estimated births to women living with HIV. This increased the estimates in some countries and decreased the values in others. There is still some work to be done to ensure the country programme data used for this calibration are robust.

Breastfeeding among women living with HIV

New analysis of survey data done in early 2019 found that women who were living with HV before widespread HIV testing and treatment had shorter breastfeeding duration. The model previously assumed that women who did not know their HIV status had similar breastfeeding patterns as women who were HIV-negative.

In 2019, eight high-burden countries in eastern southern Africa with household surveys from the early 2000s adjusted the breastfeeding duration among undiagnosed women living with HIV to reflect the new analysis. The impact of this change is reduced mother-to-child transmission during breastfeeding.

Probability of mother-to-child transmission

Analysis conducted for the UNAIDS Reference Group on Estimates, Modelling and Projections found minor updated transmission probabilities based on the latest published literature about the impact of different antiretroviral regimens on mother-to-child transmission. This had minimal impact on the child HIV estimates.

Updated age at initiation of antiretroviral therapy for children

The average age of children starting antiretroviral therapy has changed over the years as children are diagnosed earlier. Data from the IeDEA and CIPHER networks provide data on the average age of children starting antiretroviral therapy in multiple regions around the world. These data are available for each calendar year from 2002 through 2016. The most recent update of these data suggested an increase in the proportion of children under two years of age starting on treatment and a small reduction to the proportion of children older than 10 years of age starting on treatment. This has a small impact on both the number of children living with HIV and on AIDS-related deaths among children.

Retention on treatment of pregnant women

Many countries do not have robust data available on the retention of women on treatment during pregnancy. An analysis conducted for the UNAIDS Reference Group on Estimates, Modelling and Projections suggested that at the time of delivery, only 80% of women were retained on treatment. This estimate was used as a default value for women already on treatment before the pregnancy and for those women who started treatment during the pregnancy. Most of the high-burden countries in eastern and southern Africa updated this assumption to reflect available data. Previously, the default assumption was that 75% of women were retained on treatment at delivery before the pregnancy.

Changes to case surveillance and vital registration model

The age range of requested model inputs of new diagnoses, CD4 count at diagnosis and AIDS-related mortality was changed from all ages to 15 years and older. It was recommended that AIDS-related death estimates (adjusted for incomplete reporting and misclassification) rather than raw AIDS-related deaths from the vital registration system be used in the fitting process. A new function was added to estimate new diagnosis based on age, sex and year. Also, a new r-logistic fitting approach was added. Complementing this new model is another function that provides the user with the ability to determine which model best fits the inputs.

Surveillance data entered into the model

In 2018, Nigeria conducted a large household survey to improve the precision of the estimate of HIV prevalence in the country. The Nigeria AIDS Indicator and Impact Survey (NAIIS) found lower HIV prevalence than previous household surveys. The new survey estimates were included in the Nigeria Spectrum models and previous survey data were removed, resulting in a shift in HIV prevalence to a lower level over the full history of the epidemic. This change also shifted the estimated prevalence in western and central Africa to slightly lower levels.

At the global level, trends in new HIV infections, AIDSrelated deaths and people living with HIV are similar to previous estimates, although there are shifts within regions. The number of AIDS-related deaths has shifted downward in all regions due to changes in the models. New HIV infections are slightly flatter than estimated in 2018 in Asia and the Pacific and in eastern Europe and central Asia. Lower estimates of people living with HIV in western and central Africa were offset by higher estimates in Asia and the Pacific.

More detailed information on revisions to the 2019 model and Spectrum generally can be found at www.epidem.org.

PUBLICATION OF COUNTRY-SPECIFIC ESTIMATES

UNAIDS aims to publish estimates for all countries with populations of 250 000 or more ((according to the United Nations Population Division 2017 World Population Prospects). For the countries with populations of 250 000 or more that did not submit estimates, UNAIDS developed estimates using the Spectrum software based on published or otherwise available information. These estimates contributed to regional and global totals but were not published as country-specific estimates.

In countries with low-level epidemics, the number of pregnant women living with HIV is difficult to estimate. Many women living with HIV in these countries are sex workers or people who use drugs—or they are the sexual partners of people who use drugs or gay men and other men who have sex with men—making them likely to have different fertility levels than the general population. UNAIDS does not present estimates of mother-to-child HIV transmission, including estimates related to children in some countries that have concentrated epidemics, unless adequate data are available to validate these estimates. UNAIDS also does not publish estimates related to children for countries where the estimated number of pregnant women living with HIV is less than 50. With regard to reporting incidence trends, if there are not enough historical data to state with confidence whether a decline in incidence has occurred, UNAIDS will only publish data for the most recent year. This is done to prevent users from making inaccurate inferences about trends. Specifically, incidence trends are not published if there are fewer than four data points for the key population or if there have been no data for the past four years for countries using repeated survey or routine testing data. Trends prior to 2000 are not published for countries using case surveillance models if there are no early case surveillance or mortality data available.

Finally, UNAIDS does not publish country estimates when further data or analyses are needed to produce justifiable estimates. More information on the UNAIDS estimates and the individual Spectrum files for most countries can be found in the UNAIDS website. Data from the estimates can be found in the AIDSinfo section of the UNAIDS website (http://aidsinfo.unaids.org).

PART 2. METHODS FOR DERIVING THE 90–90–90 TARGETS

INTRODUCTION

Since 2015, UNAIDS has reported estimates of global, regional and country-specific progress against the 90–90–90 targets. Progress toward these targets is monitored using three basic indicators:

- Indicator 1 (the first 90): The percentage of people living with HIV who know their HIV status.
- Indicator 2 (the second 90): The percentage of people living with HIV who know their status and are accessing treatment.
- Indicator 3 (the third 90): The percentage of people living with HIV on treatment who have suppressed viral loads.

Indicators 2 and 3 can also be expressed as a percentage of all people living with HIV. When numbers or coverage of the treatment target are expressed relative to the total number of people living with HIV, this is called "the HIV testing and treatment cascade."—therapy Annual estimates of antiretroviral therapy coverage among people living with HIV are available from the time when treatment was first introduced in countries.

DATA SOURCES FOR CONSTRUCTING COUNTRY MEASURES

Country-level progress against the 90–90–90 targets was constructed using reported data from Spectrum, the Global AIDS Monitoring tool and (for selected countries in western and central Europe)) the Dublin Declaration monitoring process. Estimates are published for all people and separately, by sex, for children (0 to 14 years) and for adults (15 years and older). Upper and lower ranges of uncertainty for country-level estimates were calculated from the range of estimated numbers of people living with HIV. This range may not fully capture uncertainty in the reported estimates. A description of the target-related indicators that countries report against is provided in the UNAIDS 2019 Global AIDS Monitoring guidelines (1). Data sources are also briefly described. A summary of the number of countries that are publicly reporting on each measure is provided in Table 18.1, organized by region.

The final set of country measures of progress against the 90–90–90 targets for 2015 through 2018 are available at http://aidsinfo.unaids.org. Not all countries were able to report against all three prongs of the 90–90–90 targets: complete treatment cascades are published for 60 countries in 2018, up from 23 in 2015.

Estimates of people living with HIV

All progress measures in this report are based on UNAIDS global, regional and country-specific modelled estimates from Spectrum of the numbers of people living with HIV. Estimates of people living with HIV in 2018 were available for 170 of 193 countries and territories and published for 137. Estimates of people living with HIV are developed for all countries with populations above 250 000.

More details about how UNAIDS derives estimates and uncertainty bounds around the number of people living with HIV can be found in Part 1 of this annex. Published country estimates of people living with HIV (available http://aidsinfo.unaids.org)the) represent 79% of the total global estimated number of people living with HIV in 2018.

Knowledge of HIV status among people living with HIV

Estimates of the number of people living with HIV who know their status were derived using the most recent HIV surveillance, programme data and nationally representative population-based survey data, and from modelled 2018 estimates for 102 countries. Where data were available separately for children (aged 0–14 years) and adults (aged 15 years and older, by sex), the ageand sex-specific measures were first calculated and then aggregated to produce a national measure.

For 74 countries in 2018—primarily outside of eastern and southern Africa and western and central Africa the number of people living with HIV who knew their HIV status is based on HIV surveillance case notification data, programme registers or modelled estimates derived from case surveillance data. If the estimate from these sources was lower than the number of people accessing antiretroviral therapy, the reported value was excluded. For countries using HIV surveillance or programme data, a country should have included this measure only if the HIV surveillance system had been functioning since at least 2013 and people who have died, emigrated or who otherwise have been lost to follow-up are removed.

Although HIV surveillance systems, including those based on programme registers, can be a reasonably robust source of data to estimate the number of people living with HIV who know their status, biases in the reported numbers may still exist. For example, a country's measure of the knowledge of status may be underestimated if not all people diagnosed are reported to the surveillance system in a timely manner; the measure also may be overestimated if people are reported to the system or included on a register more than once and these duplicates are not detected. Similarly, if people die or emigrate but are not removed from the system, the number of people living with HIV who are reported to know their HIV status also will be overstated.

For 28 countries in eastern and southern Africa and western and central Africa, estimates of the numbers of people living with HIV who knew their status were derived using a new UNAIDS-supported mathematical model called the First 90 model. This model uses population-based survey and HIV testing service program data—together with country-specific HIV epidemic parameters from the standard UNAIDS Spectrum model—to produce outputs of knowledge of HIV status for adults, by sex. More details on the modelling approach are available in a forthcoming article (currently in press) *(2)*.

Knowledge of HIV status from the First 90 model for eastern and southern Africa and western and central Africa has a number of strengths compared with UNAIDS' previously recommended approach to estimating knowledge of status relying on population survey data and programme treatment coverage data. Most importantly, the new model differentiates in the population survey data those who are aware of their HIV status and those who likely seroconverted after their last HIV-negative test based on national incidence trends. This approach constrains the upper bound of the proportion of people living with HIV ever tested in the survey who likely knew their HIV status at the time of the survey, thus producing a more accurate estimate of the first 90. Results of the proportion of people who know their HIV status from the model are also available by sex, assuming male-to-female testing ratios have remained relatively constant over time. Estimates of knowledge of status by sex for adults are also available since 2010.

An important model limitation, similar to the previously recommended approach, is that caution should be used in interpreting results when the last populationbased survey was conducted more than five years ago or if there are concerns about the accuracy of self-reported testing history in the survey. Model results also are only for those aged 15 years and older. UNAIDS continues to recommend that countries conservatively estimate knowledge of status among children as the proportion of children living with HIV on treatment (unless other information from case surveillance data are available). Additional strengths and limitations of the model are described in the forthcoming article referenced earlier in this section.

People accessing antiretroviral therapy

Global and regional measures of antiretroviral therapy numbers are abstracted from country-reported programme data through the UNAIDS-supported Spectrum software, the Global AIDS Monitoring reporting tool, and the Dublin Declaration reporting process. In 2018, 143 countries had publicly available estimates of the number of people on treatment, representing 85% of all people on treatment. For the small number of countries where reported numbers of people on treatment are not available in selected years-primarily in western and central Europe and North America, and inin China, India and the Russian Federation—estimates of the number of people on treatment are developed either in consultation with the public health agency responsible for monitoring the national treatment programme or based on published sources.

In partnership with UNICEF, WHO, the Government of the United States, the Global Fund and other partners that support treatment service delivery in countries, UNAIDS annually reviews and validates treatment numbers reported by countries through Global AIDS Monitoring and Spectrum. UNAIDS staff also provide technical assistance and training to country public health and clinical officers to ensure the quality of the treatment data reported. Nevertheless, this measure may overestimate the number of people on treatment if people who transfer from one facility to another are reported by both facilities. Similarly, coverage may be overestimated if people who have died, disengaged from care or emigrated are not identified and removed from treatment registries. Treatment numbers also may be underestimated if not all clinics report the numbers on treatment completely or in a timely manner.

In 2016, UNAIDS completed a triangulation of data to verify the UNAIDS global estimate of people accessing antiretroviral therapy at the end of 2015. Since early 2017, UNAIDS and other international partners have supported more than 15 countries, primarily in sub-Saharan Africa, to verify that the number of people reported to be currently on treatment is accurate. For more details about how confident UNAIDS is in reported treatment numbers, please see *How many people living with HIV access treatment?*⁴

People who have achieved viral suppression

Progress towards the viral suppression target among people on treatment and as a proportion of all people living with HIV was derived from data reported in Spectrum and through the online Global AIDS Monitoring reporting tool and the Dublin Declaration reporting process. For the purposes of reporting, the threshold for suppression is a viral load of less than 1000 copies per ml, although some countries may set lower thresholds or require persons to achieve an undetectable viral load. This guidance also specifies only a person's last test result from the reporting year be submitted, so the reported number suppressed among those tested should represent people and not tests performed.

UNAIDS2019 Global AIDS Monitoring guidelines were revised from those of 2018 to clarify that countries should report viral load suppression outcomes, regardless of testing coverage. However, viral load testing results will only be published in countries where access to testing is for all or nearly all (>90%) people on treatment or nationally representative (typically 50–90% testing coverage). Table 1 shows the increase in the number of countries able to report on viral load suppression compared to previous years. In 2015, only 26 countries had reliable estimates; in 2018, there were 76 countries with reported data.

For countries with nationally representative but not universally accessible access to treatment, the estimate of viral suppression among those tested (i.e., the third 90) was multiplied by the number of people on treatment to obtain overall viral suppression levels in the country. Countries where testing coverage was 90% or higher reported only the number suppressed among all people on treatment.

A number of challenges exist in using country-reported data to monitor the viral load suppression target. First, routine viral load testing may not be offered at all treatment facilities, and those facilities that do offer it may not be representative of the care available at facilities without viral load testing. By assuming that the percentage of people suppressed among those accessing viral load testing is representative of all people on treatment countries that do not have complete access to testing, the measure may be overestimated or underestimated (depending on the characteristics of the reporting clinics).

⁴ The document is available at http://www.unaids.org/en/resources/documents/2016/how-many-people-living-with-HIV-access-treatment.

Another challenge in measuring the accuracy of viral load suppression estimates is that UNAIDS guidance requests routine (i.e., annual) viral load testing results only for people who are on treatment and eligible for testing. If people newly initiated on treatment achieve viral suppression but have not yet been offered viral load testing, they will be incorrectly counted as not suppressed, and the resulting viral suppression estimate will be understated. UNAIDS also requests countries to only report results from routine viral load testing: if countries report test results primarily performed because of suspected treatment failure, the number of people virally suppressed in these countries will be underestimated. UNAIDS validates country submissions for quality, but it is not always possible to identify cases where both routine and other types of testing are occurring. Finally, UNAIDS guidance recommends reporting viral load test results only for people on antiretroviral therapy; persons who are not on treatment and naturally suppress the virus will not be included in this measure.

METHODS FOR CONSTRUCTION THE 90–90–90 TREATMENT TARGET AT THE REGIONAL AND GLOBAL LEVELS

All programme data submitted to UNAIDS were validated by UNAIDS and its partners prior to publication. Country-submitted data that did not meet the required validation checks for quality either at the indicator level or across the treatment cascade were not included in the composite regional or global measures.

To estimate regional and global progress against the 90–90–90 targets, UNAIDS imputed missing country data for the first and third 90 targets using a Bayesian hierarchical model with uncertainty based on regional trends, sex differences and country-specific data for those countries reporting data for some but not all years. Additional details on the modelling approach are available in a forthcoming article (4). The proportion of data on knowledge of status and viral load suppression that was imputed by region from 2015 to 2018 are shown in Table 18.2.

Due to large differences in the proportion of people virally suppressed in western and central Europe and the United States for the years in which data were available, sub-regional estimates for North America and western and central Europe were separately calculated and then combined to estimate the western and central Europe and North America regional results at large. Upper and lower ranges of uncertainty around the global and regional estimates of the HIV testing and treatment cascade are provided that reflect uncertainty in the number of people living with HIV and uncertainty (from missing country data) in the number of people who know their HIV status and the number of people who are virally suppressed. Based on reports from data quality reviews prior to 2017, uncertainty from possible overreporting or underreporting of treatment numbers of 0.88 and 1.04 for the lower and upper bounds, respectively, was added to the bounds of treatment

coverage among people living with HIV and the second and third 90s. Upper and lower ranges of uncertainty for the 90s do not capture uncertainty in the reported or missing programme data on the numbers of people who know their HIV status or the number of people on treatment who are virally suppressed.

As in previous years, results of global and regional progress towards the 90–90–90 treatment target presented in this report supersede all previously published estimates. The new approach to modelling the global and regional estimates of the first and third 90s builds on the previous UNAIDS approach, which was to calculate missing -data for countries using the ratio of knowledge of status and treatment for the first 90 and the ratio of the number of people suppressed among those on treatment in the region for countries where data were available. One of the benefits of the new approach is that it can use reported data when they are available to estimate trends in and across the region. Also, it is now possible to measure progress separately among adults by sex.

As with the previous approach, one primary drawback to the model is that it is difficult to quantify the extent to which progress in countries that reported data to UNAIDS is similar to that of countries without data in the region. This is particularly true for viral load suppression estimates, where reported data in some regions—especially in 2015 and 2016—are limited. For example, no countries in the Caribbean in 2015 were able to meet the threshold coverage of 50% testing coverage for reporting estimates of viral load suppression. In Asia and the Pacific, national-level estimates of viral load suppression are not available in any year for India and prior to 2018 for China. As access to viral load testing improves over time, the accuracy of the estimates of the third 90 will improve. TABLE 18.2 Proportion of imputed data used to estimate the regional and global measures of the percentage of people living with HIV who know their HIV status and the percentage of people living with HIV on treatment who are virally suppressed

PART 3. DATA ON KEY POPULATIONS

DISTRIBUTION OF NEW HIV INFECTIONS BY SUBPOPULATION

The distribution of new HIV infections among subpopulations globally and by region was estimated based on data for 177 countries using five data sources.

For countries that model their HIV epidemic based on data from subpopulations, including key populations, the numbers of new infections were extracted from Spectrum 2019 files. This source provided data for sex workers from 59 countries, for people who inject drugs from 37 countries, for gay men and other men who have sex with men from 61 countries, and for transgender people from 19 countries (all of which were located in Latin America, the Caribbean and Asia and the Pacific). Additionally, 22 countries (mostly from Asia and the Pacific) had data from clients of sex workers.

The second source was mode of transmission studies conducted in countries between 2006 and 2012. The proportions of new infections estimated for each subpopulation, calculated by modes of transmission analyses, were multiplied by the number of total new gender-specific adult infections (among those aged 15–49 years) to derive an estimated number of new infections by subpopulation. This source provided data for sex workers from 18 countries, for people who inject drugs from 25 countries, and for gay men and other men who have sex with men from 22 countries.

New HIV infections for European countries with neither of the aforementioned data sources were derived from the European Centre for Disease Prevention and Control (ECDC) and WHO Regional Office for Europe HIV/AIDS surveillance in Europe 2017–2018 data (4). The proportions of new diagnoses for each region in Europe (western, central and eastern) were applied to UNAIDS estimates of new infections in each country for people who inject drugs, gay men and other men who have sex with men, and transgender people. Data for sex workers were not available from the ECDC report. New HIV infections in China, India, the Russian Federation and the United States were taken from the most recent available national reports of new diagnoses.

New HIV infections among countries without a direct data source were calculated from regional benchmarks. The benchmarks were set by the median proportion of new infections in the specific subpopulation in all available countries in the same region. The majority of these countries were located in sub-Saharan Africa. There were 112 countries that used benchmark values for the sex work estimate, 92 countries for the people who inject drugs estimate, 69 countries for the gay men and other men who have sex with men estimate, and 82 countries for the transgender people estimate.

The calculated proportions of infections for each key population include the sex partners of members of key populations. New infections among sex partners of key populations were estimated using the number of sex partners and transmission probabilities from the literature.

QUALITY OF POPULATION SIZE ESTIMATES

The regional sections of this report include tables on the estimated size of key populations. These data are based on values reported through Global AIDS Monitoring in 2018. A comprehensive review of the data was conducted during this reporting round and therefore estimates should not be compared with data presented in previous UNAIDS' reports. As a result of this process, the estimates reported can be categorized as follows:

- "National population size estimate" refers to estimates that are empirically derived using one of the following methods: multiplier, capture-recapture, mapping/enumeration, network scale up method (NSUM) or population-based survey, or respondent driven sampling-successive sampling (RDS-SS).
 Estimates had to be national or a combination of multiple sites with a clear approach to extrapolating to a national estimate.
- "Local population size estimate" refers to estimates that are empirically derived using one of the before mentioned methods but only for a subnational group of sites that are insufficient for national extrapolation.
- "Insufficient data" refers either to estimates derived from: expert opinions, Delphi, wisdom of crowds, programmatic results or registry, regional benchmarks or unknown methods or estimates derived prior to 2010. Estimates may or may not be national.
